Placenta Praevia & Accreta Spectrum Clinical Pathway .....	10
Prenatally Diagnosed Vasa Praevia Care Pathway.....	11

**1. Purpose**

To provide guidance to staff on the management of the care of women diagnosed with, or who present with, abnormalities of placental implantation.

**2. Scope**

All Lakes District Health Board medical and midwifery staff, Lead Maternity Carers (LMC), and nursing staff working in the Emergency Department, Birthing Unit, or Perinatal Unit at both Rotorua and Taupo Hospitals.

Te Whatu Ora Health NZ Lakes Maternity Service		Key Word(s): Placenta, Praevia, Accreta		Document Number: 2651616	
Authorised by: Maternity CQI	Issue Date: October 2022	Review Date: October 2024	Version: 1.0	Page: 1 of 11	

### 3. Definitions

<b>Low Lying Placental</b>	When pregnancy is more than 16 weeks gestation and the placental edge is less than 20 millimetres (2 centimetres) from the internal cervical os on transabdominal or transvaginal ultrasound scan.
<b>Placenta Praevia</b>	When the placenta lies directly over the internal cervical os.
<b>Placenta Accreta</b>	When the placenta is morbidly adhered to the uterine wall; includes the spectrum of placenta accreta, increta and percreta as it penetrates through the decidua basalis then through the myometrium and potentially into surrounding organs. For ease of description the term 'accreta' is used in this guideline for all these conditions.  Occurs when the placenta is located over a previous scar and is therefore increasingly common due to the number of previous caesarean sections.  Has increased risk of massive obstetric haemorrhage at birth and associated morbidity and mortality.
<b>Vasa Praevia</b>	Fetal vessels coursing through the membranes over or within 2 centimetres of the internal cervical os and below the fetal presenting part, unprotected by placental tissue or the umbilical cord.

### 4. Screening and Diagnosis

#### Clinical Suspicion – Placenta Praevia

While a definitive diagnosis of the position of a placenta is now achieved with ultrasound imaging, clinical acumen remains vitally important in suspecting and managing placenta praevia.

- Placenta praevia should be considered in any woman with painless and unprovoked vaginal bleeding after 20 weeks' gestation.
- At term, a high presenting part or an abnormal lie with painless and unprovoked bleeding should raise a high suspicion of placenta praevia.

This should be suspected irrespective of previous imaging results.

Where possible prior imaging should be reviewed and, if possible, undertake further imaging to confirm the location of the placenta.

Te Whatu Ora Health NZ Lakes Maternity Service		Key Word(s): Placenta, Praevia, Accreta		Document Number: 2651616	
Authorised by: Maternity CQI	Issue Date: October 2022	Review Date: October 2024	Version: 1.0	Page: 2 of 11	

### Ultrasound Imaging

Requests for USS should include relevant clinical information i.e. previous caesarean section or uterine scar.

The location of the placenta should be included in the 20 week anatomy scan. If there is suspicion of low-lying placenta or an anterior placenta over a previous uterine scar, then a further trans-abdominal ultrasound scan using the full bladder technique should be performed.

Condition	Test
<ul style="list-style-type: none"> <li>If a woman is symptomatic: →</li> </ul>	perform imaging as appropriate
<ul style="list-style-type: none"> <li>Low lying placenta with no symptoms: →</li> </ul>	follow-up scan at 36 weeks
<ul style="list-style-type: none"> <li>Placenta praevia with no symptoms: →</li> </ul>	follow-up scan at 32 – 36 weeks to clarify the diagnosis and allow time to plan for third trimester management and birth
<ul style="list-style-type: none"> <li>Placenta located over previous caesarean or other uterine scar: →</li> </ul>	refer to High Risk USS Clinic 26 - 28 weeks to rule out accreta, especially if anterior placenta praevia

A transvaginal ultrasound scan may be required for all women diagnosed at the anatomy scan as having a placenta that reaches or covers the cervical os to enable visualisation of the lower placental edge.

### Morbidly Adherent Placenta

Antenatal imaging by Colour Flow Doppler Ultrasonography should be performed in women with placenta praevia who are at increased risk of placenta accreta i.e. previous uterine scar.

Magnetic Resonance Imaging (MRI) and Doppler Ultrasound are equally effective in detecting the morbidly adherent anterior placenta. MRI is helpful in detecting the depth of placental infiltration and the adherence of a posterior placenta.

Definitive diagnosis of the type of the morbidly adherent placenta can only be made intraoperatively and histologically.

## 5. Antenatal Management

---

### Consultant review and ongoing input

Women who are found to have the placenta lying over the old scar or who have placenta praevia should be seen in antenatal clinic after confirmation via USS and have a documented antenatal discussion with a **Consultant Obstetrician** after the second scan (i.e. approximately 32 weeks) to;

- make plans for antenatal care and further imaging
- outline the possible implications for birth – mode of birth, bleeding, blood transfusion, anaesthetic and surgical measures
- determine the woman's wishes for future fertility and discuss the risk of requiring a hysterectomy
- enable multidisciplinary preparation for birth
- preparation for the birth itself

Since it is possible that birth may need to take place as an emergency caesarean section, a **clear care plan needs to be placed in the clinical notes, preferably using the Placenta Praevia and Accreta Clinical Pathway (See Appendices.)**

---

### Avoid/treat anaemia

All women should have their full/complete blood count checked, but it is particularly important for those at increased risk of obstetric haemorrhage. Be aware that serum Vitamin B12 is commonly low despite normal tissue levels in pregnancy. Treat any anaemia according to the Lakes Maternal Iron Optimisation Guideline (1401933).

---

### Timing of follow-up scan and further imaging

Placenta praevia at 32 weeks' gestation is likely to persist in 90 per cent of cases therefore a scan should be performed around 36 weeks' gestation, and prior to birth to exclude the cases where the placenta has migrated.

---

### Location for birth

Consideration should be given to the appropriate location for birth based on the clinical situation (e.g. BMI, location and severity of placenta praevia, previous surgeries, any suspicion of placenta accreta).

If there are any safety concerns, birth should take place in a tertiary hospital after referral by the Lakes Obstetric team;

- Women with other or multiple co-morbidities and are therefore at high risk of complications and heavy bleeding should be managed in a tertiary unit.

Te Whatu Ora Health NZ Lakes Maternity Service		Key Word(s): Placenta, Praevia, Accreta		Document Number: 2651616	
Authorised by: Maternity CQI	Issue Date: October 2022	Review Date: October 2024	Version: 1.0	Page: 4 of 11	

- Cell salvage is not available in Rotorua. Consideration should be given to referral to a tertiary hospital for any patient at high risk of needing cell salvage and for women who may decline blood products.
- All known cases of placenta accreta/increta/percreta should be planned to be managed in a tertiary unit – Urology and Interventional Radiology services are not available at Rotorua Hospital.

---

### Mode of birth

This will depend on the degree and location of the placenta praevia, ultrasound scan findings, other clinical factors and the woman’s preference.

- Women with a low lying placenta in the third trimester are recommended to have birth by caesarean section, especially if the placenta is thick.
- Vaginal birth may be considered in specific cases of low lying placenta, with caution, if the woman is motivated and depending on ultrasound scan findings and after discussion with a Consultant Obstetrician.
- In cases of placenta praevia, elective caesarean section should be offered as the preferable mode of birth.
- Where there is suspected placenta accreta/increta/percreta elective caesarean section at a tertiary unit should be offered as the preferable mode of birth.

---

### Gestational age of elective birth

- **Low Lying Placenta:** plan for elective caesarean section at 38 weeks.
- **Placenta Praevia:** plan for elective caesarean section at 36 – 38 weeks’ gestation
- **Placenta Accreta:** Although there is no international agreement on the timing, in cases of known placenta accreta, an elective caesarean section between 36 and 37 weeks’ gestation, at tertiary unit, is advised to avoid labour and an emergency procedure.
- **Complicated, High Risk Praevia or Accreta:** If high risk of bleeding (e.g., previous self-limited episodes of antepartum haemorrhage or contractions) or higher levels of surgical difficulty (i.e. percreta), planning caesarean section at 34-35 weeks or earlier, at a tertiary unit, is reasonable.

Overall, timing needs to be individualised depending on the clinical picture and resources available.

Te Whatu Ora Health NZ Lakes Maternity Service		Key Word(s): Placenta, Praevia, Accreta		Document Number: 2651616	
Authorised by: Maternity CQI	Issue Date: October 2022	Review Date: October 2024	Version: 1.0	Page: 5 of 11	

---

**Inpatient management**

Inpatient management is recommended for patients with placenta praevia with antepartum haemorrhage (APH) in the third trimester.

- A current group and hold should be available for all women admitted with APH and known placenta praevia.
- Women should be encouraged to stay hydrated, remain mobile, and wear TED stockings. Prophylactic low molecular weight heparin should be considered for women at high risk of thromboembolism.

Antepartum haemorrhage should be managed in accordance with the Lakes Antepartum Haemorrhage Guideline 2499506.

**6. Multidisciplinary pre-operative planning**

This should be planned and coordinated by the Consultant Obstetrician.

---

**Antenatal steroids for fetal lung maturation**

There should be good communication with the Paediatric team to ensure antenatal steroids are offered and recommended if any episodes of bleeding at <34+6 weeks' gestation.

Repeated doses of steroids are appropriate if recurrent episodes of bleeding occur <32 weeks or birth is planned <35 weeks.

---

**Blood availability**

There should be consultation with a Haematologist and communication with Blood Bank to allow cross-matched red cells to be available during an antenatal inpatient admission or for birth, and other products as necessary.

If there are known blood antibodies, a referral at 28-32 weeks to Blood Bank with the date of the caesarean section is needed.

Te Whatu Ora Health NZ Lakes Maternity Service		Key Word(s): Placenta, Praevia, Accreta		Document Number: 2651616	
Authorised by: Maternity CQI	Issue Date: October 2022	Review Date: October 2024	Version: 1.0	Page: 6 of 11	

## 7. Surgical Procedures

An experienced Obstetrician and Anaesthetist should be present for any woman going to the operating theatre with a known placenta praevia. Consideration should be given to having another Obstetrician available to assist should the need arise.

### Unexpected diagnosis of placenta accreta/increta/percreta

In the case of an unexpected diagnosis of placenta accreta/increta/percreta at the time of surgery, consideration should be given to the safety of continuing surgery versus cessation of surgery and transfer to a tertiary unit. Involvement of a second Obstetrician and additional anaesthetic support in decision making is recommended.

In the case of an emergency surgical procedure being required for a woman at high risk of bleeding, where transfer is not possible due to patient instability, appropriate personnel should be called and be present in theatre;

- On-call Obstetrician and consider a second Obstetrician
- On-call Anaesthetist and consider a second Anaesthetist
- Consider General Surgeon
- Blood Bank
- Theatre Coordinator (with appropriate staff requested)
- Paediatric Consultant

## 8. Massive Postpartum Haemorrhage

Should be dealt with in accordance with the recommendations as for primary postpartum haemorrhage – see the Ministry of Health ‘[Treating Postpartum Haemorrhage Poster](#)’ and the Lakes Adult Massive Transfusion Protocol (MTP) – Rotorua 585349.

In the event of life-threatening haemorrhage, appropriate and timely recourse to a peripartum hysterectomy is a life-saving measure.

## 9. Vasa Praevia

### Prenatal Diagnosis and Care

- Ultrasound detection of vasa praevia at the time of the anatomy scan has a high diagnostic accuracy and a low false positive rate
- To avoid unnecessary admission, anxiety, iatrogenic preterm birth, and caesarean section, persistence of vasa praevia must be confirmed on ultrasound in the third trimester
- The ultimate goal in vasa praevia cases is to facilitate birth prior to rupture of membranes whilst minimising the impacts of prematurity. Based on available data, planned birth via caesarean section is recommended at 34-36 weeks of gestation in asymptomatic women
- Women with known vasa praevia at 32 weeks should be given prophylactic corticosteroids due to the increased risk of fetal compromise and preterm birth
- Women with confirmed vasa praevia should be admitted to a tertiary hospital from 32 weeks' gestation as decided on a case-by-case basis and combination of risk factors, including multiple pregnancy etc.
- Women with resolved vasa praevia (>2cm from os) should receive ongoing monitoring

See the Prenatally Diagnosed Vasa Praevia Care Pathway (Appendix 2.)

### Intrapartum Diagnosis

- Birth via emergency caesarean section and neonatal resuscitation, including the use of blood transfusion if required, are the standard of care for management of vasa praevia diagnosed during labour.
- Birth should not be delayed whilst trying to confirm the diagnosis.

### Suspected Ruptured Vasa Praevia

- The paediatric team, including the on-call Paediatrician, should be requested to be present at birth and the blood bank should be urgently contacted to ready red blood cells for neonatal transfusion
- Placental pathological examination should be requested to confirm the diagnosis, especially when stillbirth has occurred or when there has been acute fetal compromise

## 10. Audit Indicators

- Percentage of women with placenta praevia or suspected placenta accreta whose care has followed this guideline
- Percentage of women with placenta praevia or suspected placenta accreta who have the Placenta Praevia & Accreta Clinical Pathway available in their notes from 32 weeks onwards
- Percentage of women with placenta praevia or suspected placenta accreta that required emergency birth prior to the planned procedure, who had plans for both emergency and planned birth discussed and documented
